Timing Rayleigh Quotient minimization in R

true

2023-9-6

Abstract

This vignette is simply to record the methods and results for timing various Rayleigh Quotient minimizations with R using different functions and different ways of running the computations, in particular trying Fortran subroutines and the R byte compiler. It has been updated from a 2012 document to reflect changes in R and its packages that make it awkward to reprocess the original document on newer computers.

The computational task

The maximal and minimal eigensolutions of a symmetric matrix A are extrema of the Rayleigh Quotient

$$R(x) = (x'Ax)/(x'x)$$

We could also deal with generalized eigenproblems of the form

$$Ax = eBx$$

where B is symmetric and positive definite by using the Rayleigh Quotient (RQ)

$$R_a(x) = (x'Ax)/(x'Bx)$$

In this document, B will always be an identity matrix, but some programs we test assume that it is present.

Note that the objective is scaled by the parameters, in fact by by their sum of squares. Alternatively, we may think of requiring the **normalized** eigensolution, which is given as

$$x_{normalized} = x/sqrt(x'x)$$

Timings and speedups

In R, execution times can be measured by the function system.time, and in particular the third element of the object this function returns. However, various factors influence computing times in a modern computational system, so we generally want to run replications of the times. The R packages rbenchmark and microbenchmark can be used for this. I have a preference for the latter. However, to keep the time to prepare this vignette with Sweave or knitR reasonable, many of the timings will be done with only system.time.

There are some ways to speed up R computations.

- The code can be modified to use more efficient language structures. We show some of these below, in particular, to use vector operations.
- We can use the R byte code compiler by Luke Tierney, which has been part of the R distribution since version 2.14.
- We can use compiled code in other languages. Here we show how Fortran subroutines can be used.

Our example matrix

We will use a matrix called the Moler matrix Nash (1979, Appendix 1). This is a positive definite symmetric matrix with one small eigenvalue. We will show a couple of examples of computing the small eigenvalue solution, but will mainly perform timings using the maximal eigenvalue solution, which we will find by minimizing the RQ of (-1) times the matrix. (The eigenvalue of this matrix is the negative of the maximal eigenvalue of the original, but the eigenvectors are equivalent to within a scaling factor for non-degenerate eigenvalues.)

Here is the code for generating the Moler matrix.

However, since R is more efficient with vectorized code, the following routine by Ravi Varadhan should do much better.

```
molerfast <- function(n) {
# A fast version of `molermat'
    A <- matrix(0, nrow = n, ncol = n)
    j <- 1:n
    for (i in 1:n) {
        A[i, 1:i] <- pmin(i, 1:i) - 2
    }
    A <- A + t(A)
    diag(A) <- 1:n
    A
}</pre>
```

Time to build the matrix

Let us see how long it takes to build the Moler matrix of different sizes. In 2012 we used the byte-code compiler, but that now seems to be active by default and NOT to give worthwhile improvements. We also include times for the eigen() function that computes the full set of eigensolutions very quickly.

```
## Loading required package: microbenchmark

osize - matrix size in bytes

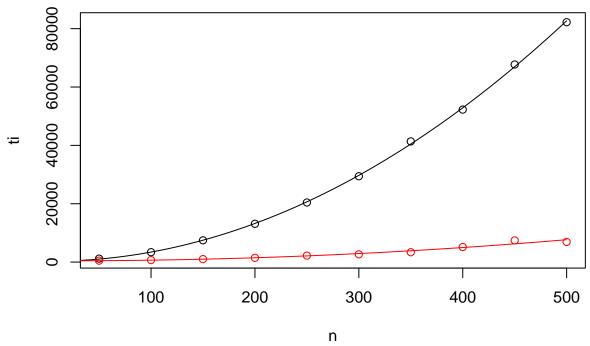

```
## eigentime - all eigensolutions time
## buildi - interpreted build time, range
## bfast - interpreted vectorized build time
## Times converted to milliseconds
```

It does not appear that the compiler has much effect, or else it is being automatically invoked.

We can graph the times. The code, which is not echoed here, also models the times and the object size created as almost perfect quadratic models in n.

Execution time vs matrix size

Computing the Rayleigh Quotient

The Rayleigh Quotient requires the quadratic form x'Ax divided by the inner product x'x. R lets us form this in several ways.

```
rqdir<-function(x, AA){
    rq<-0.0
    n<-length(x) # assume x, AA conformable
    for (i in 1:n) {
        for (j in 1:n) {
            rq<-rq+x[i]*AA[[i,j]]*x[j]
        }
    }
    rq
}</pre>
```

Somewhat better (as we shall show below) is

```
ray1<-function(x, AA){
    rq<- t(x)%*%AA%*%x
}</pre>
```

and (believed) better still is

```
ray2<-function(x, AA){
    rq<- as.numeric(crossprod(x, crossprod(AA,x)))
}</pre>
```

Note that we could implicitly include the minus sign in these routines to allow for finding the maximal eigenvalue by minimizing the Rayleigh Quotient of -A. However, such shortcuts often rebound when the

implicit negation is overlooked.

If we already have the inner product \$ A x\$ as vector ax from some other computation, then we can simply use

```
ray3<-function(x, AA, ax=axftn){
    # ax is a function to form AA%*%x
    rq<- - as.numeric(crossprod(x, ax(x, AA)))
}</pre>
```

Matrix-vector products

In generating the RQ, we do not actually need the matrix itself, but simply the inner product with a vector x, from which a second inner produce with x gives us the quadratic form \$ x' A x\$. If n} is the order of the problem, then for largen', we avoid storing and manipulating a very large matrix if we use implicit inner product formation. We do this with the following code. For future reference, we include the multiplication by an identity.

```
ax<-function(x, AA){
   u<- as.numeric(AA%*%x)
}

axx<-function(x, AA){
   u<- as.numeric(crossprod(AA, x))
}</pre>
```

Note that second argument, supposedly communicating the matrix which is to be used in the matrix-vector product, is ignored in the following implicit product routine. It is present only to provide a common syntax when we wish to try different routines within other computations.

```
aximp<-function(x, AA=1){ # implicit moler A*x
    n<-length(x)
    y<-rep(0,n)
    for (i in 1:n){
        tt<-0.
        for (j in 1:n) {
            if (i == j) tt<-tt+i*x[i]
            else tt<-tt+(min(i,j) - 2)*x[j]
        }
        y[i]<-tt
    }
    y
}
ident<-function(x, B=1) x # identity</pre>
```

However, Ravi Varadhan has suggested the following vectorized code for the implicit matrix-vector product.

```
axmolerfast <- function(x, AA=1) {
# A fast and memory-saving version of A%*%x
# For Moler matrix. Note we need a matrix argument to match other functions
n <- length(x)
j <- 1:n
ax <- rep(0, n)
for (i in 1:n) {
term <- x * (pmin(i, j) - 2)
ax[i] <- sum(term[-i])
}</pre>
```

```
ax <- ax + j*x
ax
}</pre>
```

We can also use external language routines, for example in Fortran. However, this needs a Fortran **subroutine** which outputs the result as one of the returned components. The subroutine is in file moler.f.

```
subroutine moler(n, x, ax)
      integer n, i, j
      double precision x(n), ax(n), sum
      return ax = A * x for A = moler matrix
C.
      A[i,j]=min(i,j)-2 for i<>j, or i for i==j
      do 20 i=1,n
         sum=0.0
         do 10 j=1,n
            if (i.eq.j) then
               sum = sum + i * x(i)
                sum = sum + (min(i,j)-2)*x(j)
            endif
 10
         continue
         ax(i)=sum
      continue
 20
      return
      end
```

This is then compiled in a form suitable for R use by the command (this is a command-line tool, and was run in Ubuntu Linux in a directory containing the file moler.f but outside this vignette):

```
R CMD SHLIB moler.f
```

This creates files moler.o and moler.so, the latter being the dynamically loadable library we need to bring into our R session.

```
dyn.load("moler.so")
cat("Is the mat multiply loaded? ",is.loaded("moler"),"\n")

## Is the mat multiply loaded? TRUE

axftn<-function(x, AA=1) { # ignore second argument
    n<-length(x) # could speed up by having this passed
    vout<-rep(0,n) # purely for storage
    res<-(.Fortran("moler", n=as.integer(n), x=as.double(x), vout=as.double(vout)))$vout
}</pre>
```

We can also byte compile each of the routines above

Now it is possible to time the different approaches to the matrix-vector product.

```
dyn.load("moler.so")
cat("Is the mat multiply loaded? ",is.loaded("moler"),"\n")
```

```
## Is the mat multiply loaded? TRUE
```

                                                                   1110
## ax = R matrix * vector A %*% x
## axx = R crossprod A, x
## axftn = Fortran version of implicit Moler A * x
## aximp = implicit moler A*x in R
## axmfast = A fast and memory-saving version of A %*% x
## Times in milliseconds from microbenchmark
```

From the above output, we see that the crossprod variant of the matrix-vector product appears to be the fastest. However, we have omitted the time to build the matrix. If we must build the matrix, then we need somehow to include that time. Apportioning "fixed costs" to timings is never a trivial decision. Similarly if, where and how to store large matrices if we do build them, and whether it is worth building them more than once if storage is an issue, are all questions that may need to be addressed if performance becomes important.

```

```

Out of all this, we see that the Fortran implicit matrix-vector product is the overall winner at all values of n. Moreover, it does NOT require the creation and storage of the matrix. However, using Fortran does involve rather more work for the user, and for most applications it is likely we could live with the use of either

- the interpreted matrix-product based on crossprod and an actual matrix is good enough, especially if a fast matrix build is used and we have plenty of memory, or
- the interpreted or byte-code compiled implicit matrix-vector multiply axmolerfast.

RQ computation times

We have set up three versions of a Rayleigh Quotient calculation in addition to the direct form. The third form is set up to use the axftn routine that we have already shown is efficient. We could also use this with the implicit matrix-vector product axmolerfast.

It seems overkill to show the RQ computation time for all versions and matrices, so we will do the timing simply for a matrix of order 500.

```
## Direct algorithm: 17567.68
## ray1: mat-mult algorithm: 239.4928
## ray2: crossprod algorithm: 234.7876
## ray3: ax Fortran + crossprod: 659.3261
## ray3: ax fast R implicit + crossprod: 5567.37
```

Here we see that the use of either the matrix multiplication in ray1 or of crossprodinray2is very fast, and this is interpreted code. Once again, we note that all timings except those forray3should have some adjustment for the building of the matrix. If storage is an issue, thenray3, which uses the implicit matrix-vector product in Fortran, is the approach of choice. My own preference would be to use this option if the Fortran matrix-vector product subroutine is already available for the matrix required. I would not, however, generally choose to write the Fortran subroutine for a "new" problem matrix. The fast implicit matrix-vector tool withray3' is also useful and quite fast if we need to minimize memory use.

Solution by spg

To actually solve the eigensolution problem we will first use the projected gradient method spg from BB. We repeat the RQ function so that it is clear which routine we are using.

```
# spgRQ.R
molerfast <- function(n) {
    # A fast version of `molermat'
    A <- matrix(0, nrow = n, ncol = n)
    j <- 1:n
    for (i in 1:n) {
        A[i, 1:i] <- pmin(i, 1:i) - 2
    }
}</pre>
```

```
A \leftarrow A + t(A)
 diag(A) <- 1:n
}
rqfast<-function(x){
 rq<-as.numeric(t(x) %*% axmolerfast(x))</pre>
 rq
}
rqneg<-function(x) { -rqfast(x)}
proj <- function(x) {sign(x[1]) * x/sqrt(c(crossprod(x))) } # from ravi</pre>
# Note that the c() is needed in denominator to avoid error msgs
require(BB)
## Loading required package: BB
n<-100
x \leftarrow rep(1,n)
x<-x/as.numeric(sqrt(crossprod(x)))</pre>
AA<-molerfast(n)
teig<-microbenchmark(evs<-eigen(AA), times=mbt)$time</pre>
cat("eigen time =", mean(teig)*0.001,"\n")
## eigen time = 1558.793

Solution by other optimizers

We can try other optimizers, but we must note that unlike spg they do not take account of the scaling. However, we can build in a transformation, since our function is always the same for all sets of parameters scaled by the square root of the parameter inner product. The function nobj forms the quadratic form that is the numerator of the Rayleigh Quotient using the more efficient code{crossprod() function

```
rq<- as.numeric(crossprod(y, crossprod(AA,y)))
but we first form
y<-x/sqrt(as.numeric(crossprod(x)))
to scale the parameters.</pre>
```

Since we are running a number of gradient-based optimizers in the wrapper optimx::opm(), we have reduced the matrix sizes and numbers.

```
require(optimx)

## Loading required package: optimx

nobj<-function(x, AA=-AA){
    y<-x/sqrt(as.numeric(crossprod(x)))
    rq<- as.numeric(crossprod(y, crossprod(AA,y)))
}</pre>
```

```
ngrobj<-function(x, AA=-AA){</pre>
   y<-x/sqrt(as.numeric(crossprod(x)))
  n<-length(x)
  dd<-sqrt(as.numeric(crossprod(x)))</pre>
  T1<-diag(rep(1,n))/dd
  T2 < x\%0\%x/(dd*dd*dd)
  gt<-T1-T2
  gy<- as.vector(2.*crossprod(AA,y))
  gg<-as.numeric(crossprod(gy, gt))</pre>

```

The timings for these matrices of order 20 to 100 are likely too short to be very reliable in detail, but do show that the RQ problem using the scaling transformation and with an analytic gradient can be solved very quickly, especially by the limited memory methods such as L-BFGS-B and ncg. Below we use the latter to show the times over different matrix sizes.

```
ctable<-matrix(NA, nrow=10, ncol=2)
nmax<-10
for (ni in 1:nmax){
   n<-50*ni
   x<-runif(n) # generate a vector
   AA<-molerfast(n) # define matrix
   tcgu<-microbenchmark(arcgu<-optimr(x, fn=nobj, gr=ngrobj, method="ncg",</pre>
```

```
AA=-AA), times=mbt)
  ctable[[ni,1]]<-n
  ctable[[ni,2]] <-mean(tcgu$time)*0.001
cgtime<-data.frame(n=ctable[,1], tcgmin=ctable[,2])</pre>
print(round(cgtime,0))

Let us check that the solution for n = 100 by Geradin is consistent with the answer via eigen().
n<-100
x<-runif(n)
# emax<-load("temax.Rdata")</pre>
evalmax <- emax $evalmax
evecmac<-emax$evecmax
ogaxftn<-geradin(x, naxftn, ident, AA=1, BB=1, control=list(trace=FALSE))
gvec <- ogaxftn $x
gval<- -ogaxftn$RQ</pre>
gvec<-sign(gvec[[1]])*gvec/sqrt(as.numeric(crossprod(gvec)))</pre>
diff<-gvec-evecmax
cat("Geradin diff eigenval from eigen result: ",gval-evalmax," max(abs(vector diff))=",
                     max(abs(diff)), "\n")
```

Geradin diff eigenval from eigen result: -6.758855e-06 max(abs(vector diff))= 8.150972e-06

Perspective

We can compare the different approaches by looking at the ratio of the best solution time for each method (compiled or interpreted, with best choice of function) to the time for the Geradin approach for the different matrix sizes. In this we will ignore the fact that some approaches do not build the matrix.

Ratio of eigensolution times to Geradin routine by matrix size

To check the value of the Geradin approach, let us use a much larger problem, with n=2000.

```
## Times in seconds
```

Build = 82435948 eigen(): 7295583870 Rcgminu: 286467271 Geradin: 370713834

Ratios: build= 0.2223708 eigen= 19.67983 Rcgminu= 0.772745

Conclusions}

The Rayleigh Quotient minimization approach to eigensolutions has an intuitive appeal and seemingly offers an interesting optimization test problem, especially if we can make it computationally efficient. To improve time efficiency, we can apply the R byte code compiler, use a Fortran (or other compiled language) subroutine, and choose how we set up our objective functions and gradients. To improve memory use, we can consider using a matrix implicitly.

From the tests in this vignette, here is what we may say about these attempts, which we caution are based on a relatively small sample of tests:

- The R byte code compiler offers a useful gain in speed when our code has statements that access array elements rather than uses them in vectorized form.}
- The crossprod() function is very efficient.
- Fortran is not very difficult to use for small subroutines that compute a function such as the implicit matrix-vector product, and it allows efficient computations for such operations.
- The eigen() routine is a highly effective tool for computing all eigensolutions, even of a large matrix. It is only worth computing a single solution when the matrix is very large, in which case a specialized method such as that of Geradin makes sense and offers significant savings, especially when combined with the Fortran implicit matrix-product routine.

Acknowledgements

This vignette originated due to a problem suggested by Gabor Grothendieck. Ravi Varadhan has provided inciteful comments and some vectorized functions which greatly altered some of the observations.
